Introduction to Keras

Joe Yeh, M.D.

What is Keras?

- Keras is a high-level neural networks API, written in Python and capable of running on top of <u>TensorFlow</u>, <u>CNTK</u>, or <u>Theano</u>. It was developed with a focus on enabling fast experimentation. *Being able* to go from idea to result with the least possible delay is key to doing good research.
- Use Keras if you need a deep learning library that:
 - Allows for easy and fast prototyping (through user friendliness, modularity, and extensibility).
 - Supports both convolutional networks and recurrent networks, as well as combinations of the two.
 - Runs seamlessly on CPU and GPU.

Two Modes of Keras

- Sequential
 - Straightforward, for a linear stack of layer
- Functional
 - For more complex, arbitrary computation graph

Sequential Model

Getting started with the Keras Sequential model

The Sequential model is a linear stack of layers.

You can create a Sequential model by passing a list of layer instances to the constructor:

```
from keras.models import Sequential
from keras.layers import Dense, Activation

model = Sequential([
    Dense(32, input_shape=(784,)),
    Activation('relu'),
    Dense(10),
    Activation('softmax'),
])
```

You can also simply add layers via the .add() method:

```
model = Sequential()
model.add(Dense(32, input_dim=784))
model.add(Activation('relu'))
```

Functional API for Model Construction

Model class API

In the functional API, given some input tensor(s) and output tensor(s), you can instantiate a Model via:

```
from keras.models import Model
from keras.layers import Input, Dense

a = Input(shape=(32,))
b = Dense(32)(a)
model = Model(inputs=a, outputs=b)
```

Methods of a Model

- Compile: Configure model for training compile(self, optimizer, loss=None, metrics=None, loss_weights=None, sample_weight_mode=None, weighted_metrics=None, target_tensors=None)
- Fit: Trains the model for a fixed number of epochs fit(self, x=None, y=None, batch_size=None, epochs=1, verbose=1, callbacks=None, validation_split=o.o, validation_data=None, shuffle=True, class_weight=None, sample_weight=None, initial_epoch=o, steps_per_epoch=None, validation_steps=None)
- Evaluate: Returns the loss value & metrics values
 evaluate(self, x=None, y=None, batch_size=None, verbose=1, sample_weight=None, steps=None)

Training

Keras models are trained on Numpy arrays of input data and labels. For training a model, you will typically use the fit function. Read its documentation here.

 After a model is constructed either using sequential model or functional API, the compile, fit and evaluate methods are the same.
